

Exercise: Write a function to reverse a vector.

```
void reverse (vector<int> & V)
```

```
{
    size_t n = V.size();
    for (size_t i = 0; i < n/2; i++) {
        // swap V[i] <math>\leftrightarrow</math> V[n-i-1]
        int temp = V[i];
        V[i] = V[n-i-1];
        V[n-i-1] = temp;
    }
}
```

$V[0] \leftrightarrow V[n-1]$

$V[1] \leftrightarrow V[n-2]$

\vdots
 $V[i] \leftrightarrow V[n-i-1]$

Usage:

```
int main ()
{
    vector<int> V = {2, 4, 6, 8, 10};
    reverse(V);
    // Now V = {10, 8, 6, 4, 2}
```

$V[0]$ $V[1]$ $V[2]$

Example: Binary search.

```
bool search(const vector<int>& v, int x)
```

```
{ // is  $x \in v$ ? answer  $\approx \log_2 n$  steps
```

```
  // Note: v must be sorted!
```

```
  int mid = v.size()/2;
```

```
  if ( $x < v[mid]$ )
```

```
    // search  $v[0, \dots, mid-1]$ 
```

```
  else if ( $x > v[mid]$ )
```

```
    // search  $v[mid+1, \dots, v.size()-1]$ 
```

```
  else
```

```
    return true;
```
